1. Introduction

Seismic phase data, location details and magnitudes are presented for all earthquakes detected and located by BGS during 1985. The land areas of Great Britain and Northern Ireland and their coastal waters are covered within the limits of the detection capabilities of the seismograph network. A map of seismic activity in the North Sea is included using data from the Bulletin of North Sea Earthquakes, 1985, by Newmark et al (1986).

The seismicity of the UK since 1969 is illustrated using data extracted from the previous catalogues of Burton and Neilson (1980) and Turbitt (1984, 1985).

2. Catalogue Format

2.1 Tables

Hypocentral parameters, for each earthquake, are tabulated under the headings:

| | |
|----------|---|
| Date | - day, month, year. |
| Time | - hours, minutes, seconds of origin time |
| Lat | - Latitude, positive North. |
| Lon | - Longitude, positive East. |
| KmE | - Grid reference, easting from National Grid origin near the Scilly Isles. |
| KmN | - Grid reference, northing. |
| Dep | - hypocentral depth in km, blank indicates depth unknown. Note that depths for events of quality C, D and possibly B, are unreliable due to the large errors involved. |
| RMS | - root mean square error of arrival time residuals in seconds. |
| q | - solution quality of the hypocentre based on the RMS of residuals (above), the implied errors in epicentre and depth and the number and distribution of stations. |
| Mag | - Richter local magnitude. |
| Locality | - a geographical indication of the epicentral area, usually the nearest town followed by the region. |
| Int | - Maximum felt intensity on the MSK scale (Medvedev et al, 1964), when known. + indicates that an event was reported felt at the intensity given but no survey was initiated to determine the maximum intensity. Comments and felt areas, where appropriate, are included on the next line. |

Data on the earthquakes and seismograph stations operated in 1985 are arranged as follows:

TABLE 1 is a chronological listing of all earthquakes near the UK for which a reliable epicentral location could be obtained.

TABLE 2 is a listing of the events in Table 1 arranged in order of decreasing latitude to facilitate identification of earthquakes in selected regions.

TABLE 3 is a chronological listing of events which, although detected by the seismograph network, had arrival patterns too weak to permit the computation of reliable locations. An indication of the estimated epicentre is given but errors could be very large. These events are not included in Tables 1 or 2.

TABLE 4 is an alphabetical listing of the geographic coordinates of seismograph stations operated in 1985 by BGS, DIAS and Leeds University.

TABLE 5 lists the arrival times of phases for the events in Table 1 at each station, together with amplitude information used for magnitude calculation.

TABLE 6 is the crustal seismic velocity model used for event location.

2.2 Figures

FIGURE 1: the detection threshold of the network of seismograph stations in Table 4 for average background noise conditions where the detection criterion is signal received above 4 nanometres at 10 Hz on 3 stations.

FIGURE 2: the variation of epicentral location errors within the UK area for a magnitude 2.0 earthquake.

FIGURE 3: the epicentral location map of all the events in 1985 that are listed in Table 1.

FIGURE 4: the locations of earthquakes in the UK of magnitude 2.5ML and above from 1979 to 1985.

FIGURE 5: the locations of earthquakes in the UK of magnitude 3.5ML and above from 1969 to 1985.

FIGURE 6: the locations of earthquakes in the North Sea area in 1985.

3. The BGS UK Seismograph Network

3.1 Instrumentation

A typical seismic network consists of up to seven 'outstation' vertical seismometers radio-linked over distances of up to 100 km to a central site where the data, along with that from a local 3-component set of two horizontal and one vertical seismometers, are recorded on magnetic tape by a Geostore recorder. Tapes are dispatched, usually once per week, to Edinburgh for analysis.

A more detailed description of the system is given by Browitt et al (1985) and the response of the system is described by Turbitt and Stewart (1982).

At some locations, on-line paper chart recorders display three channels to permit rapid investigation of reported felt tremors. At other stations low-gain vertical seismometers extend the dynamic range of the system to stronger motions and low frequency microphones are used to aid the discrimination of sonic booms.

The improvements in geographic coverage of the UK with the installation of more seismic networks in the last fifteen years is described in Turbitt (1985).

3.2 Detection Threshold

The detection capabilities of a network depend upon station distribution, instrument sensitivity and background noise levels. For the BGS UK network the lower limit of sensitivity is governed by the background noise level. The contours in Figure 1 illustrate the lower threshold magnitude for an earthquake to exceed 4 nanometres at 10 Hz on at least three seismographs. Noise sources such as wind, waves, traffic and livestock vary considerably with time (about 0.5 to 15 nanometres, typically at 10 Hz) causing the magnitude thresholds to increase or decrease. In conditions of high noise 0.8 ML should be added to the contour values.

The detection contours in Figure 1 hold true only if all stations are continuously monitored and this is not always the case. Small events in unmonitored areas may then go undetected unless felt and reported to BGS by local inhabitants. The detection capabilities by this process are strongly dependant on population density with the consequence that areas such as the Scottish Highlands have a high threshold magnitude when local networks are not continuously analysed.

4. Hypocentre Parameters and their Errors

4.1 Epicentre Location

By accurately timing the signal onsets at a minimum of three stations a location can be found for an earthquake which satisfies the observed pattern of arrivals. Instrumental locations in the catalogue were obtained using the computer program HYPO71 (Lee and Lahr, 1975) which iteratively adjusts a trial hypocentre (latitude, longitude, depth, and origin time) until the observed and computed arrival times coincide closely.

The accuracy of locations is dependant on distances from the closest stations, the distribution of the stations around the epicentre, the resolution to which signal onsets can be timed from the records, and the accuracy with which the seismic wave velocity through the earth can be modelled.

Figure 2 illustrates the likely variation of epicentral location errors within the UK area for a magnitude 2.0 earthquake, 5km deep. These errors have been determined by the computer program HYPOERR (Lienert et al, 1986) assuming P and S arrival time variances of 0.2 and 0.4 seconds respectively at all detecting stations. The rapid increase in epicentral uncertainty to 20 km and above is apparent as the epicentre moves beyond the detecting

range of the seismograph network. For convenience in the tables, epicentre grid references and depths have been given to 0.1 km although this accuracy does not apply in all cases.

The general velocity model used is given in Table 6 and was derived from a series of refraction profiles traversing Britain, LISPB (Bamford et al. 1976; Bamford et al, 1978; Assumpcao & Bamford, 1978). However, for some localised areas of activity, different models have been employed and these are explained in detail in BGS reports on the particular series.

4.2 Depth Determination

The accurate determination of earthquake depth presents a more difficult problem, mainly because phase arrival patterns at the seismographs can still be satisfied for a large range of depths merely by adjusting the origin time to suit. Constraints on the depth can usually only be imposed when a station is very near the epicentre and even then the accuracy depends on the velocity model.

The best depth determinations have been obtained when a series occurred almost beneath a network, as for example in the Lleyn Peninsula. Tremors in the Midlothian coalfield area usually have small depth errors due to the proximity of LOWNET stations and can be seen to lie in the first one or two kilometres near the coal workings.

For events at larger distances, depth errors may be up to tens of kilometres. The quality factor of the event as listed in the tables (*q*), is an indication of the depth error. As a general guide only A, and possibly B class events have reliable depths.

4.3 Seismicity Distribution

Owing to variability in the earthquake detection threshold, which is governed by ambient noise conditions and the geometry of the observing network (see 3.2 above), the catalogue is biased towards certain localities. In order to present a consistent picture of UK seismic activity, earthquakes with magnitude 2.5 ML or greater, in the period 1979-1985 have been plotted in Figure 4. The data set is considered complete for these magnitudes in all localities. Seismicity for 1969-1985 is shown in Figure 5 with a threshold magnitude of 3.5. This is the period covered by BGS instrumentation which consisted only of the network around Edinburgh (LOWNET) and Eskdalemuir (ESK) in the early years.

4.4 Magnitude

Almost all earthquakes in the catalogue have been assigned a local magnitude (ML) as defined by Richter (1935) :

$$ML = \log_{10}(A/A_0)$$

where *A* is the deflection (centre to peak in mm) registered by the earthquake on a Wood-Anderson seismograph and *A₀* is that for a "standard" magnitude zero earthquake at the same distance. The *A₀* term is thus a distance correction factor tabulated by Richter to 200, and later 600km,

Although Richter intended his method to be an approximate quantification of earthquake size and his attenuation term, Ao, strictly only applies to California, the formula is still used world-wide today. The ML magnitudes in this catalogue have been calculated according to Richter by converting the output of the BGS instruments to an equivalent Wood-Anderson deflection. Ideally the measurements are made on two horizontal instruments and averaged but, if this was not possible, the mean of the magnitudes from a number of verticals has been used. Ground motion registered at a seismograph varies with site conditions, direction from the earthquake, and the nature of the ray path. Consequently, it is important to take the mean from a good distribution of stations. The resulting errors on magnitudes quoted in the catalogue will normally be less than 0.4 ML.

4.5 Intensity

Intensity is a measure of the effect of the shaking on people, structures and objects. It decreases with distance from a maximum value (I_0) usually found close to the epicentre. The maximum felt intensity is quoted, where known, on the MSK scale (Medvedev et al. 1964).

5. Catalogue content and completeness

5.1 The geographical area

The catalogue covers all of the UK land mass and its coastal waters including the North Sea to 2°E and 60°N . The North Sea as a whole is covered in the BGS catalogue for that area (eg. Newmark and Turbitt, 1985 and Newmark et al., 1986).

5.2 Events included

All events believed to be due to true tectonic origins have been included. That is, events caused by natural stresses within the earth.

Coalfield events are also included. These are small events occurring near the coal workings and are believed to be caused by the redistribution of stress as the coal is extracted and subsidence takes place.

5.3 Events excluded

Events that are known, or suspected to be of explosive origin are excluded from the catalogue. Explosions due to quarrying, mining, weapon testing or disposal, naval exercises, geophysical prospecting and civil engineering are all excluded where possible. Unfortunately, identification by record character, location and time of occurrence is not always positive and some man-made events may have been included in the catalogue or, more rarely, a small natural event may have been excluded.

Acoustic disturbances, such as sonic booms from supersonic aircraft are also excluded although when felt they are included in Table 3. The air-borne waves are readily identified by their slow travel time across an array or by their signature on a microphone.

5.4 Completeness

The contours of detection threshold in Figure 1 show that the whole of the UK is covered by the seismograph network for approximately magnitude 1.7, and above, at times of low ambient noise levels. High noise levels may cause this threshold to rise to about 2.5. Normally, however, an earthquake of this size would be felt if not detected in the areas of poorer instrumental coverage. The catalogue can, therefore, be assumed to be complete for all earthquakes of magnitude 2.5 and above.

ACKNOWLEDGEMENTS

Interchange of data with the Dublin Institute of Advanced Studies, the University of Bergen, NORSAR and other European agencies through the International Seismological Centre, made the location of many of these events possible.

We are indebted to Mobil North Sea, Mobil Exploration (Norway), the Camborne School of Mines, The States of Jersey Met. Office, the Universities of East Anglia, Leeds and Leicester and many other individuals who assisted with station operation.

The work was funded in part by the Department of Energy, The Jersey New Waterworks Company, Renfrew District Council the Department of the Environment the Nuclear Installations Inspectorate, the CEGB and the Natural Environment Research Council. It is published with the approval of the Director of the British Geological Survey (NERC).

* The coordinates of this station have been revised since the publication of the last catalogue.

Agency codes:

| | |
|------|--------------------------------------|
| BGS | British Geological Survey |
| DIAS | Dublin Institute of Advanced Studies |
| LDS | University of Leeds |

Component codes:

| | |
|---|--|
| 1 | Single vertical seismometer |
| 3 | Orthogonal set of 3 seismometers |
| 4 | As in 3, above, plus one low-gain vertical |
| R | Station coordinates registered with the International Seismological Centre, England and the National Earthquake Information Centre, USA. |

KEY TO PHASE DATA ENCODING FORMAT

General description:

The format of the phase data presented here was originally designed to allow direct entry onto a computer coding sheet, of measurements taken from a seismogram generated using a magnetic tape for recording. This system is described by Browitt (1979).

Each line is coded according to the flag in column 80. Lines with 1, 2 or 3 in column 80 give epicentral details; those with a blank in column 80 contain phase information.

Epicentral details (1,2 or 3 in column 80):

| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|--|---|---|---|---|---|---|---|

Line 1

DyMoYr :Event date....Day, Month, Year.
Network :Name of network, eg LOWNET.
Tape :Analogue tape number on which event is recorded eg LN123.
S :Tape side when two sided recording selected eg 1 or 2.
Loc :Tape footage of event eg 1200.
Event :Event number on that tape eg 20.
Sec :Second length of jet-pen playout in mm, eg 12.
Ccor :Seconds error of internal clock (absolute minus clock time) eg -0.23.
Dek :Gain of replay deck eg 5.0.
Reader :Name of analyst.
T :Event type. Earthquake.. L=Local, R=Regional, T=Teleseism, E=unknown
Explosion... Q=Quarry, D=up to 10deg, A=further than 10deg
U=Unknown, S=Sonic
Locality :Closest generally known place or area, followed by region.

Line 2 (: in field indicates decimal point)

HrMnSe:c :Hours, minutes and seconds of the origin time.
Grid:e./ :Kilometres east and north of the National grid origin.
Grid:n
Dep:h :Depth of event in kilometres.
(valid for A and possibly B quality events).
M:l :Richter local magnitude obtained from the method described
in the Manual of Seismological Observatory Practice (MSOP).
B:/* :MB*, An approximation to MB as determined using stations
at closer ranges (paragraph 3.3.2 in MSOP).
M:b :Body wave magnitude determined using the method described in MSOP.
M:s :Surface wave magnitude determined using the method described in MSOP.
Io :Maximum MSK intensity. 2+ indicates felt, no macroseismic details.
3+, 4+ etc indicates felt at MSK 3 or 4, but no survey carried out.
3,4,5 etc describes the maximum MSK intensity produced by the event
Lat:... :Latitude of event in degrees and decimal degrees, positive is north
N :(N) North or (S) South. Only inserted if no Lat sign convention +/-
is in use.

Lon:... :Longitude of event in degrees and decimal degrees, negative is west
E : (E) East or (W) West. Only inserted if no Lon sign convention +/-
is in use.

Line 3

Comments : Descriptive remarks about felt area and other items of interest.
RMS and Q : See catalogue format (para 2.1, page 1).
ERH & ERZ : Standard errors in epicentre and focal depth.

Phase data (column 80 blank):

Code :Station code eg EAB.
Co :Component, Z=Vertical, NS=North-South, EW= East-West.
HrMn :Time datum, Hours and Minutes for phase arrivals. -1 in Hr column
indicates the end of the event.
Sec1 :Seconds to the first arrival. For local events this is either PN
or PG. Subsequent P arrivals are not usually read as the location
program HYPO71 does not require them.
Amp1 :Trace amplitude (mm) of first motion of this arrival, for 3-component
set.
C :Amp1 is H: half peak-peak, C: centre-peak, F or blank: peak-peak
A: log(ground amplitude in millimicrons)
P1 :Phase, normally P (= PN or PG) but any MSOB code possible.
Q :HYPO weighting factor to arrival. 0 or blank= full weighting to
4= zero weighting (ignore). 9= use P-S interval only for this line.
I :I=Impulsive (onset read better than 0.1s) or E=emergent (worse than 0.1s)
U :U=First motion up/compression or D=down/dilation.
Sec2..Amp2.CP2QIU: As for first arrival, but usually referring to S phase(SN,SG)
Amp :Trace amplitude in millimetres at the relevant part of the phase train
for the magnitude type indicated in Mt.
ML: largest amplitude in trace, MB*: Maximum in P-phase.
MB: Maximum in first 25 seconds, MS: Rayleigh phase (Z, long period)
M : Equivalent to ML, but not used in the magnitude calculation.
C :As previous
Per :Period (secs) of Amp.
Mt :Magnitude type... ML ,B*, MB, MS.
Amp.CPer.Mt: As previous
Jotp :Jet pen sensitivity in volts/cm used on playout eg 0.25,1.0,2.5,10.0
Amod :Amplifier-modulator gain. Normally 100, 200, 400. Low-gain devices
usually have a gain of 4.
P :If there is a polarity reversal in the system, this column=1.
Dist :Distance in kilometres to event from station.

PHASE DATA : 1985
